BASIC DATA AND SUMMARY OF  
GROUND-WATER RESOURCES OF CHAMBERS COUNTY, TEXAS

By

William W. Doyel, Geologist

United States Geological Survey

February 1956

ABSTRACT

Chambers County is on the upper Texas Gulf Coast about 25 miles east of Houston. The county is underlain by Tertiary and Quaternary sedimentary rocks which dip toward the coast. The principal water-bearing formations are all of Pleistocene age and are, from youngest to oldest: The Beaumont clay, the "Alta Loma" sand, and the Lissie formation.

The sands of the Beaumont clay yield small to moderate quantities of water to wells throughout the county. The water is of good chemical quality in the western and northeastern parts of the county, but the mineralization increases toward the southeast.

The "Alta Loma" sand yields water of good chemical quality to wells in the western part of the county, but the quality is poor in the eastern part. The "Alta Loma" yields large quantities of water to industrial wells at the eastern end of the Houston Ship Channel area in Harris County and probably could produce similar quantities in extreme western Chambers County.

The Lissie formation is the principal aquifer in the heavily industrialized Houston area in Harris County, but most of the sands of the Lissie contain highly mineralized water in Chambers County.

The average daily ground-water withdrawals in Chambers County in 1948 totaled about 855,000 gallons. As a result of this comparatively small rate of production, the water levels have declined only very slowly, especially in wells tapping the Beaumont clay. Wells tapping the "Alta Loma" sand have shown larger declines, principally as a result of heavy pumping in the neighboring industrialized areas in Harris County.

## INTRODUCTION

Chambers County is on the upper Texas Gulf Coast (fig. 1). It is bounded on the east by Jefferson County, on the north by Liberty County, on the west by Harris County, and on the south by Galveston County and the Gulf of Mexico. The land area of the county is 618 square miles. According to the United States Census, the population in 1950 was 7,871. The economy of the county is supported largely by the production of oil, rice, cattle, and lumber. Anahuac, population 1,282, is the county seat and largest town. Other towns are Mont Belvieu, Hankamer, and Winnie.

According to the records of the U. S. Weather Bureau, the average annual rainfall at Anahuac is 52.82 inches and the mean annual temperature is 68° F. The average monthly and annual precipitation and the average annual temperature for the periods of record are shown graphically in figure 2.

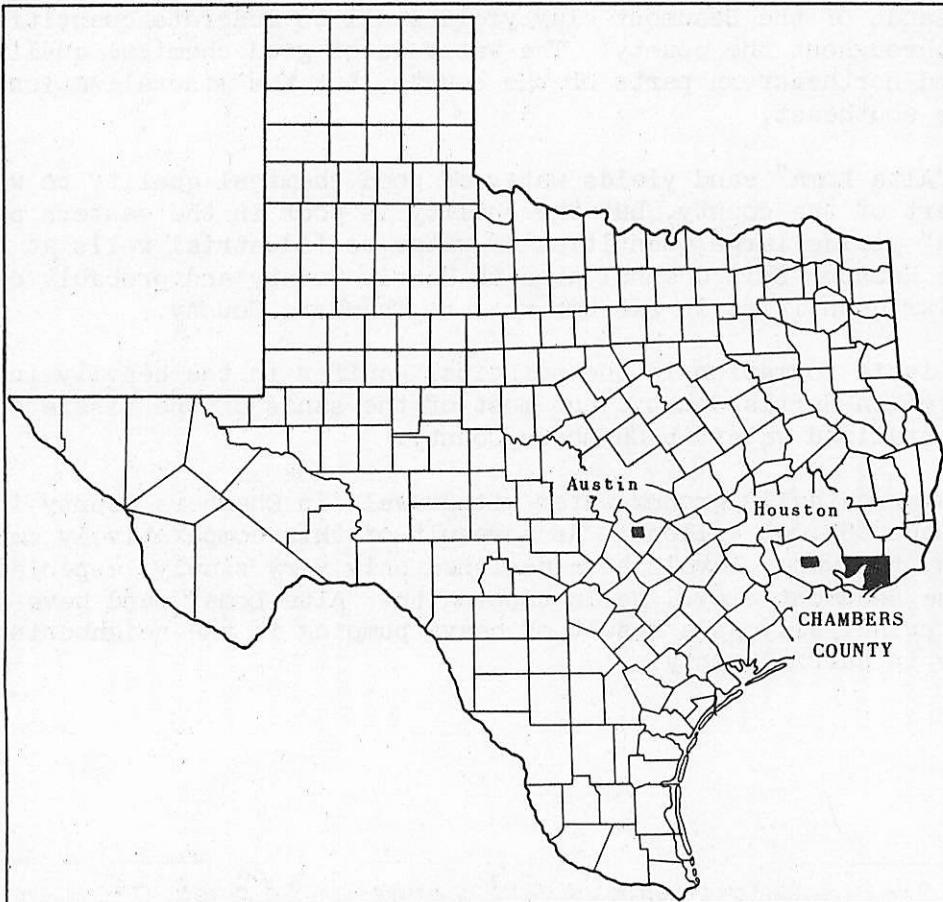

FIGURE 1.- Map of Texas showing location of Chambers County.

Texas Board of Water Engineers in cooperation with the U. S. Geological Survey

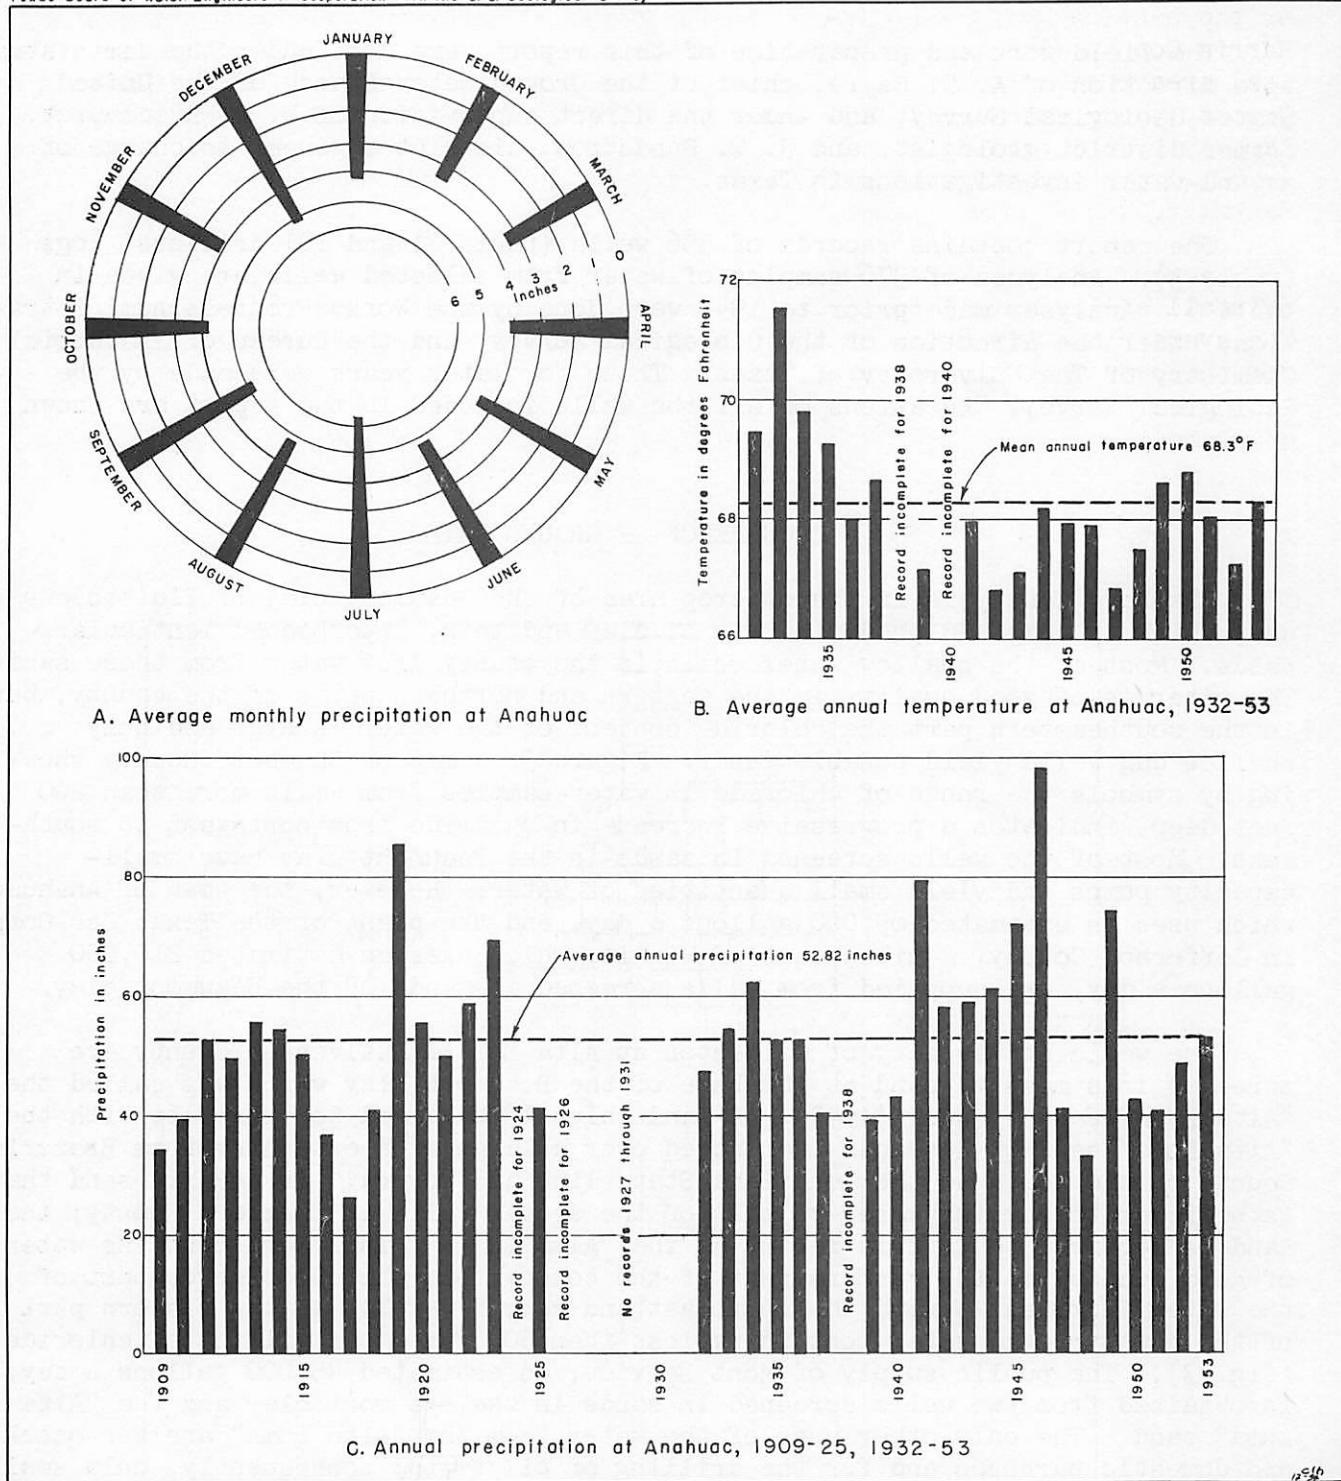

FIGURE 2.- Precipitation and temperature at Anahuac, Chambers County, Tex.

The surface of the county is nearly flat, sloping gently from an altitude of 50 feet in the northern part to sea level at the Gulf. The southern part is grass-land, but a belt of timber extends across most of the northern part. The Trinity River valley and Trinity Bay divide the county into two parts.

The field work and preparation of this report were done under the administrative direction of A. N. Sayre, chief of the Ground Water Branch of the United States Geological Survey, and under the direct supervision of W. L. Broadhurst, former district geologist, and R. W. Sundstrom, district engineer in charge of ground-water investigations in Texas.

The report contains records of 556 wells (table 2) and 101 drillers' logs (table 3). Analyses of 376 samples of water from selected wells are given in table 5. Analyses made prior to 1942 were done by the Works Progress Administration, under the direction of the Geological Survey, and the Bureau of Industrial Chemistry of The University of Texas. Those for later years were made by the Geological Survey. Locations of all the wells included in the report are shown on plate 1.

#### OCCURRENCE OF GROUND WATER

Chambers County is in the outcrop area of the Beaumont clay of Pleistocene age, which is composed predominantly of clay and thin, interbedded lenticular sands. Most of the shallow water wells in the county draw water from these sands. The water is of good quality in the western and northern parts of the county, but in the southeastern part the chloride content of the water is high and only shallow dug wells yield potable water. Figure 3, a map of Chambers County showing by symbols the range of chloride in water samples from wells more than 200 feet deep, indicates a progressive increase in chloride from northwest to southeast. Most of the wells screened in sands in the Beaumont clay have small-capacity pumps and yield small quantities of water. However, the town of Anahuac, which uses an estimated 85,000 gallons a day, and the plant of the Texas Gas Corp. in Jefferson County, 2 miles east of Winnie, which uses an estimated 210,000 gallons a day, are supplied from wells screened in sands of the Beaumont clay.

The wells of the city of Galveston at Alta Loma in Galveston County are screened in a massive sand at the base of the Beaumont clay which was called the "Alta Loma" sand by Rose (1943). A sand which is believed to correlate with the "Alta Loma" sand of Rose has been noted over a large area extending from Brazoria County on the south to the Louisiana State line and beyond. It is this sand that is believed to furnish water to most of the deeper wells in Chambers County; the sand is referred to in this report as the "Alta Loma." This sand contains water of good quality in the western part of the county, but the chloride content of the water increases toward the southeast and very few wells in the eastern part of the county yield water containing less than 500 parts per million of chloride (fig. 3). The public supply of Mont Belvieu, an estimated 45,000 gallons a day, is obtained from two wells screened in sands in the Beaumont clay and the "Alta Loma" sand. The only other uses of the water from the "Alta Loma" are for stock and domestic purposes and for the drilling of oil tests; consequently, only small-capacity wells are needed. The "Alta Loma" is, however, probably capable of yielding large quantities of water to wells in the county, particularly in the

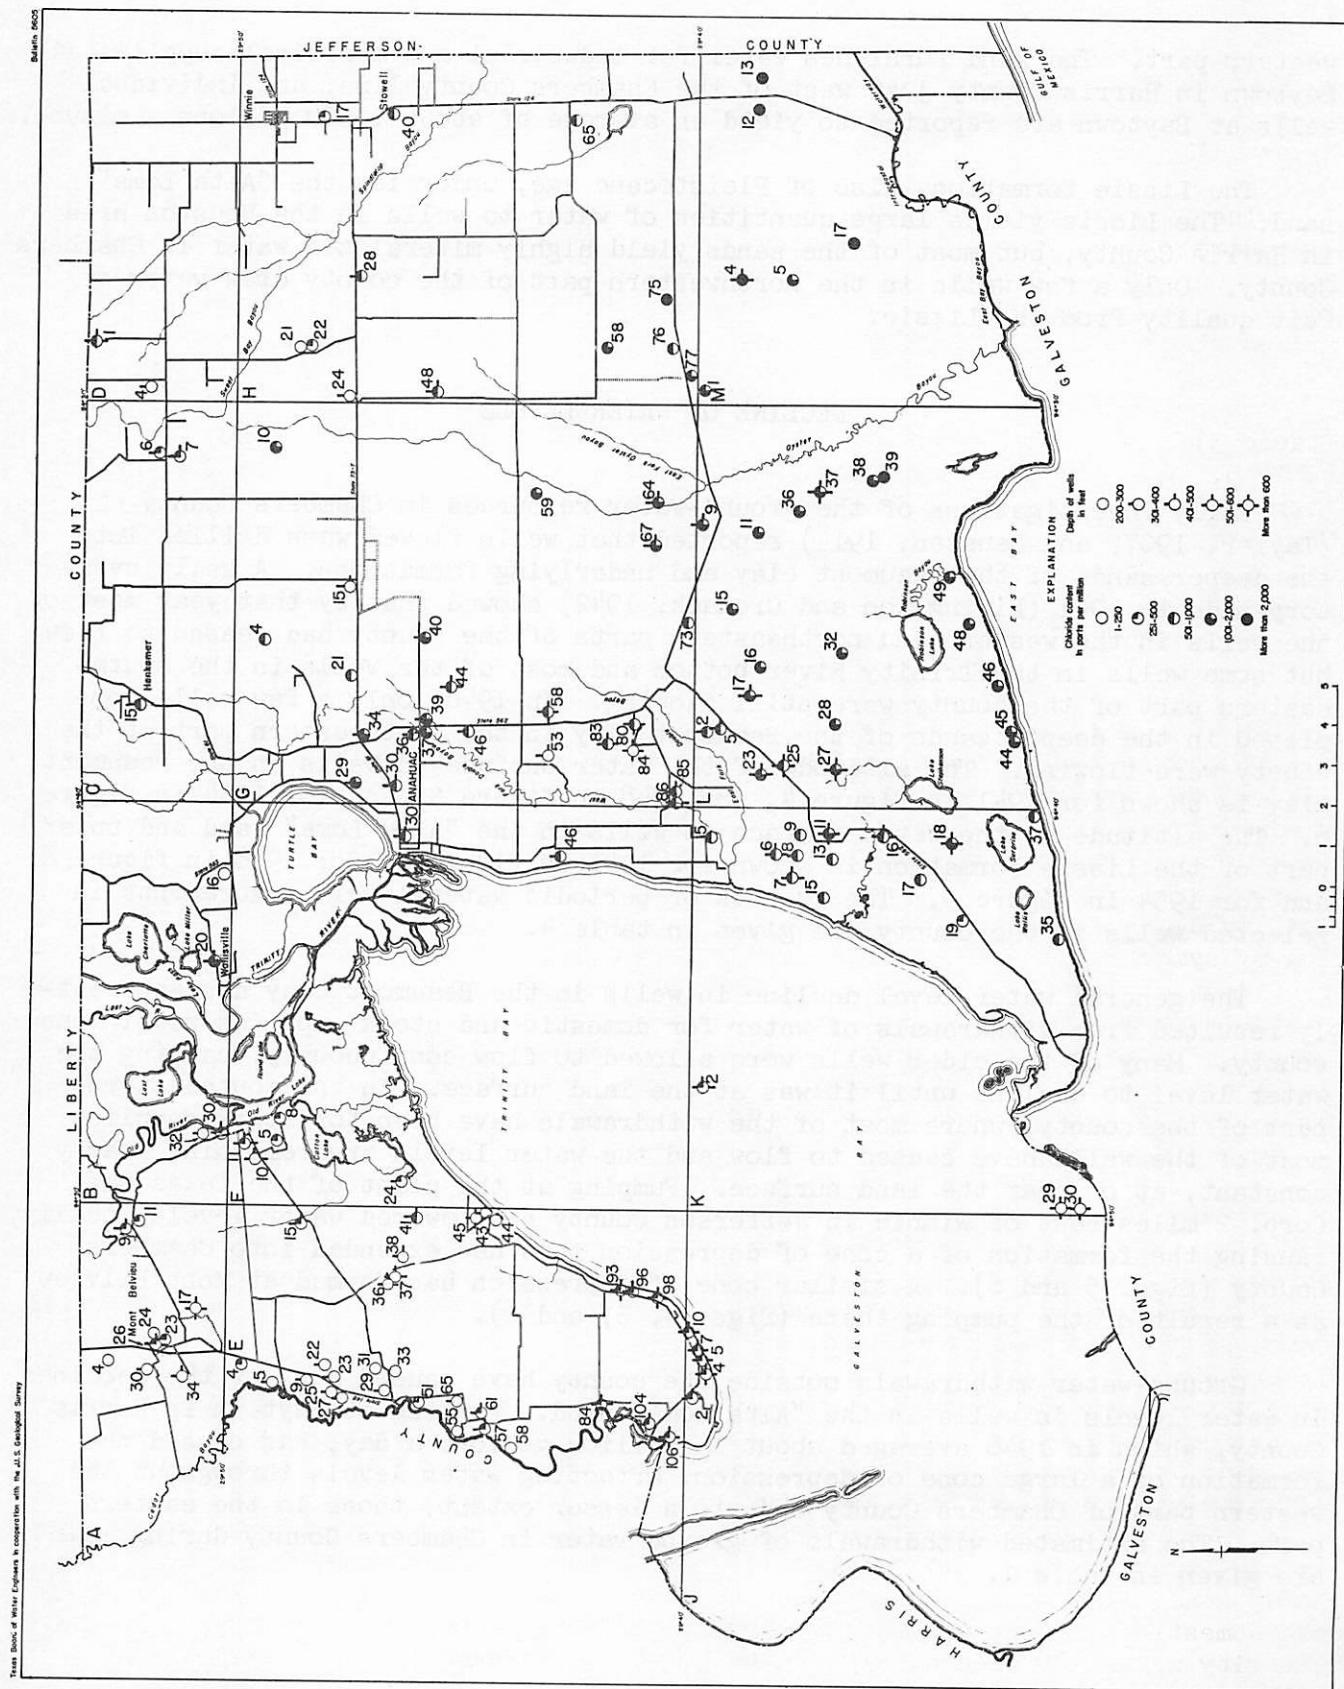

FIGURE 3-Map showing chloride content in water from selected wells in Chambers County, Tex.

western part. The sand furnishes water for industrial and municipal supplies at Baytown in Harris County just west of the Chambers County line, and individual wells at Baytown are reported to yield an average of about 1,500 gallons a minute.

The Lissie formation, also of Pleistocene age, underlies the "Alta Loma" sand. The Lissie yields large quantities of water to wells in the Houston area in Harris County, but most of the sands yield highly mineralized water in Chambers County. Only a few wells in the northwestern part of the county draw water of fair quality from the Lissie.

#### DECLINE OF WATER LEVELS

Early investigations of the ground-water resources in Chambers County (Taylor, 1907, and Deussen, 1914) reported that wells flowed when drilled into the deeper sands of the Beaumont clay and underlying formations. A well inventory made in 1941 (Livingston and Cromack, 1942) showed that by that year most of the wells in the western and northeastern parts of the county had ceased to flow, but some wells in the Trinity River bottom and most of the wells in the southeastern part of the county were still flowing. In 1948, only a few wells completed in the deeper sands of the Beaumont clay in the southeastern part of the county were flowing. The altitude of the water surface in wells in the Beaumont clay is shown for 1941 in figure 4, for 1948 in figure 5, and for 1954 in figure 6. The altitude of the water surface in wells in the "Alta Loma" sand and upper part of the Lissie formation is shown for 1941 in figure 7, for 1948 in figure 8, and for 1954 in figure 9. The results of periodic water-level measurements in selected wells in the county are given in table 4.

The general water-level decline in wells in the Beaumont clay has apparently resulted from withdrawals of water for domestic and stock supplies within the county. Many of the older wells were allowed to flow continuously, causing the water level to decline until it was at the land surface. In the southeastern part of the county, where most of the withdrawals have been for stock supplies, most of the wells have ceased to flow and the water levels are remaining nearly constant, at or near the land surface. Pumping at the plant of the Texas Gas Corp. 2 miles east of Winnie in Jefferson County has lowered water levels locally, causing the formation of a cone of depression that has extended into Chambers County (figs. 5 and 6). A similar cone of depression has formed at Mont Belvieu as a result of the pumping there (figs. 4, 5, and 6).

Ground-water withdrawals outside the county have caused most of the declines in water levels in wells in the "Alta Loma" sand. Pumping at Baytown in Harris County, which in 1948 averaged about 14 million gallons a day, has caused the formation of a large cone of depression, affecting water levels throughout the western part of Chambers County and, to a lesser extent, those in the eastern part. The estimated withdrawals of ground water in Chambers County during 1948 are given in table 1.

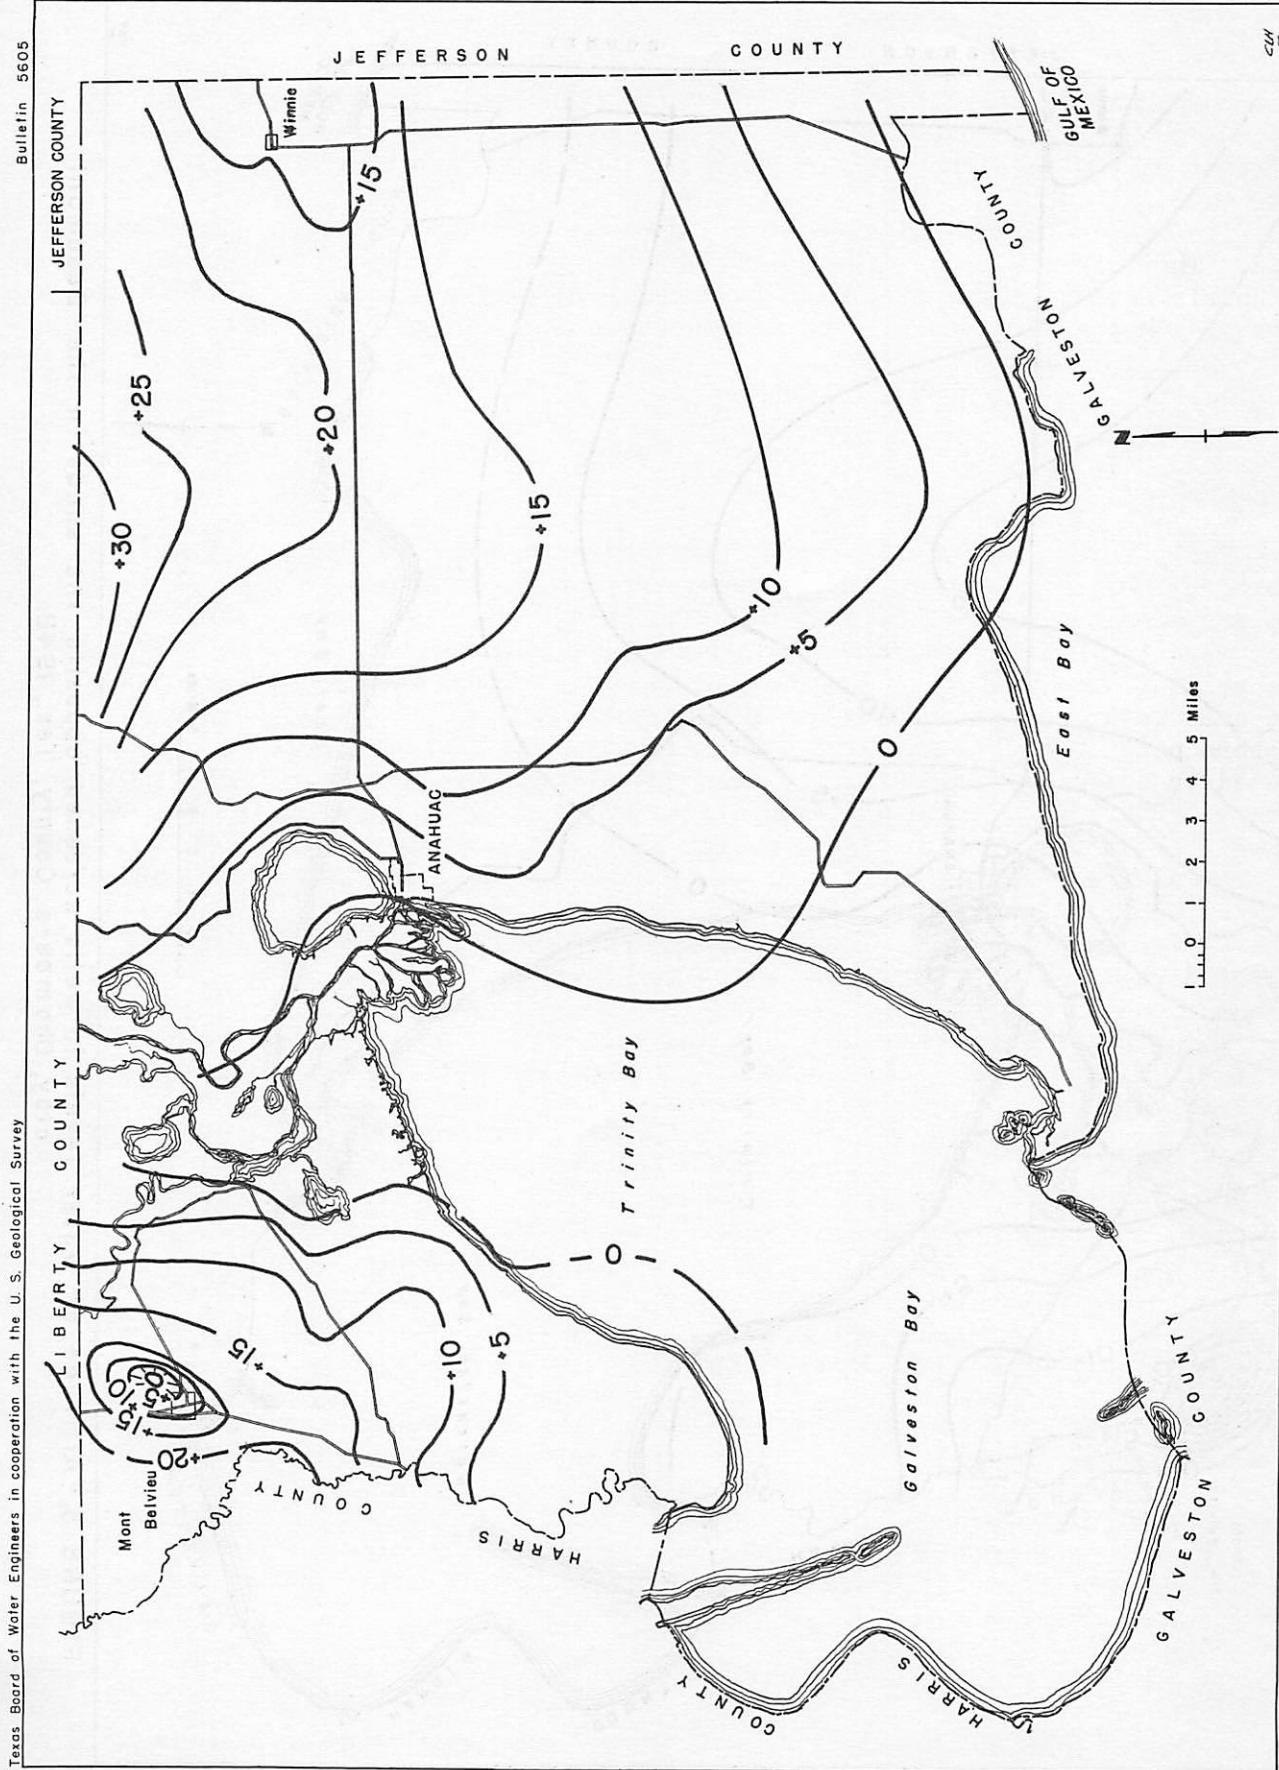

FIGURE 4.—Altitude of water levels in wells screened opposite the sands in the Beaumont clay, Chambers County, Tex., 1941.

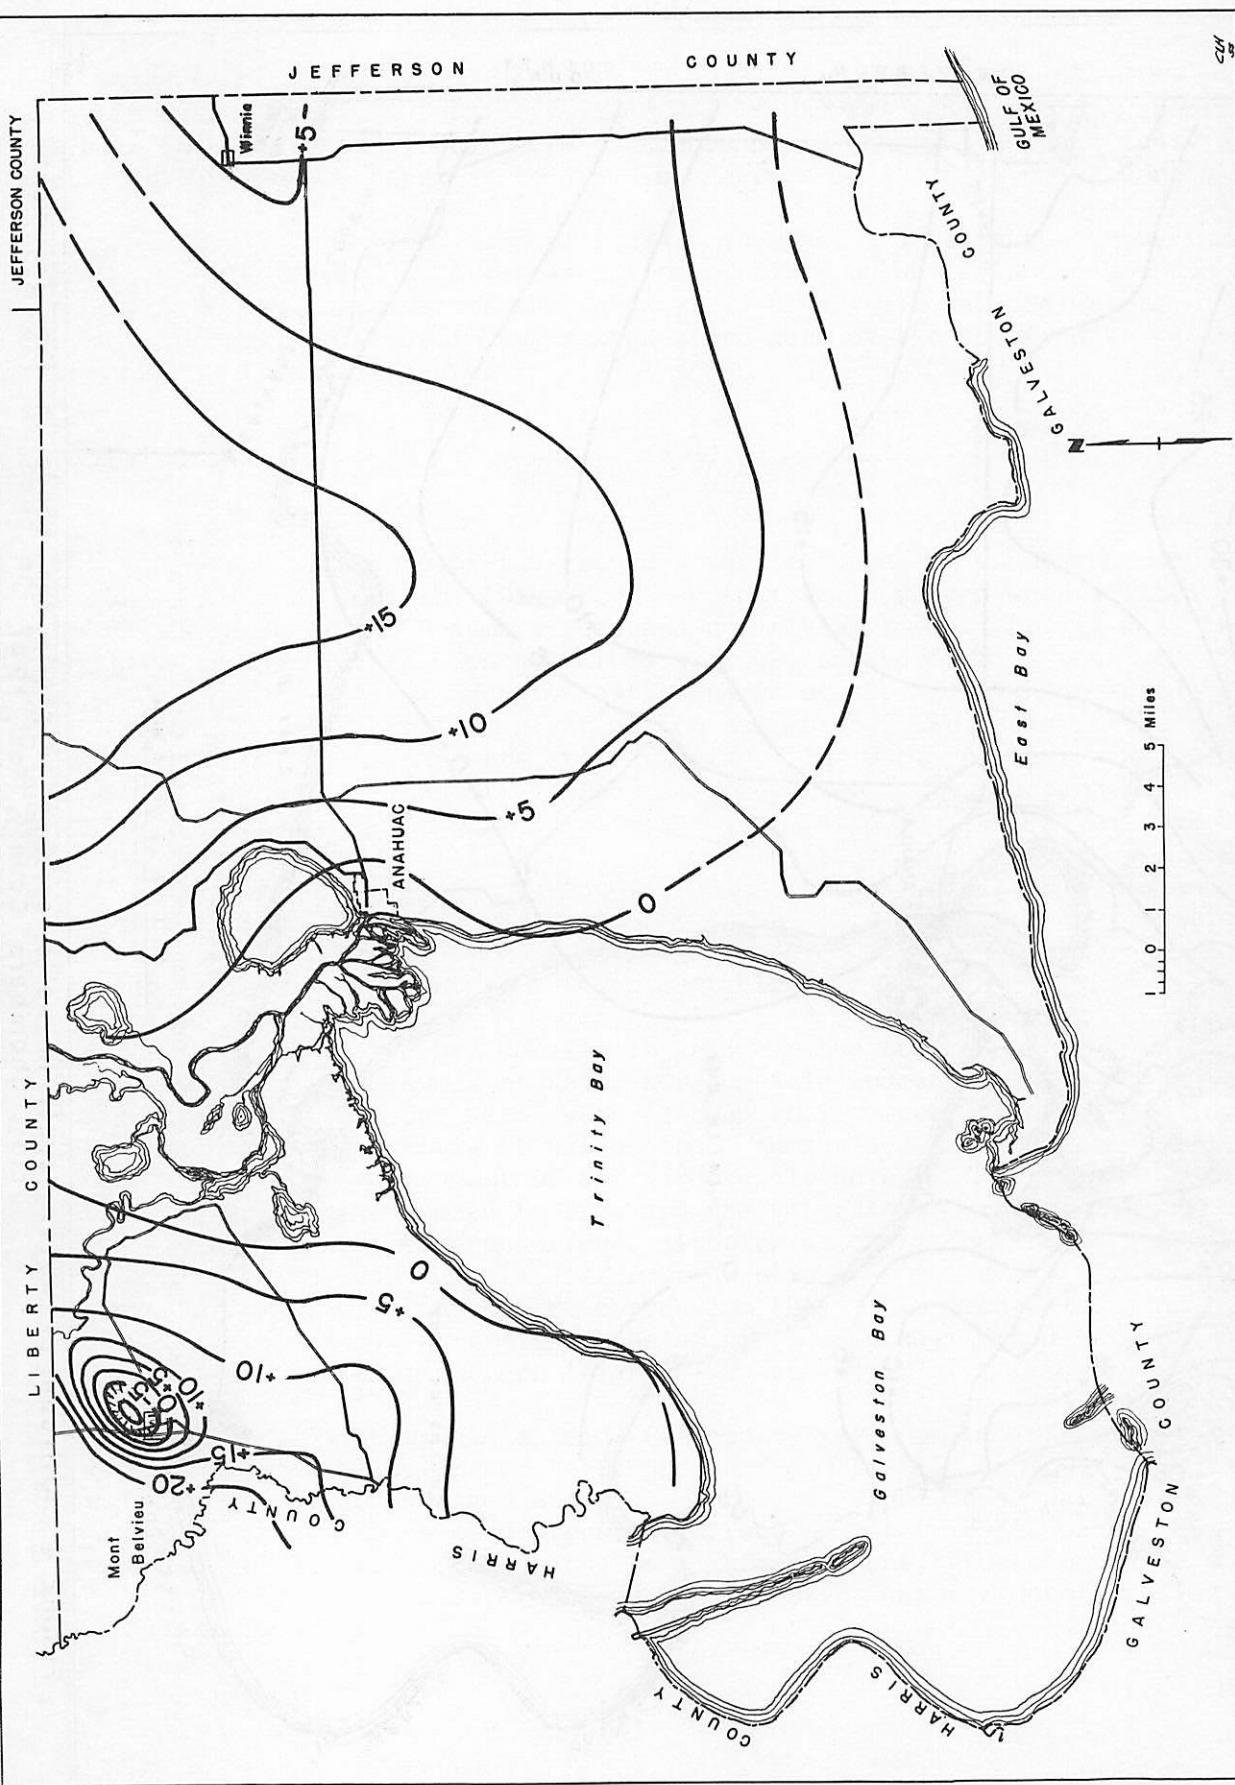

FIGURE 5.—Altitude of water levels in wells screened opposite the sands in the Beaumont clay, Chambers County, Tex., 1948.

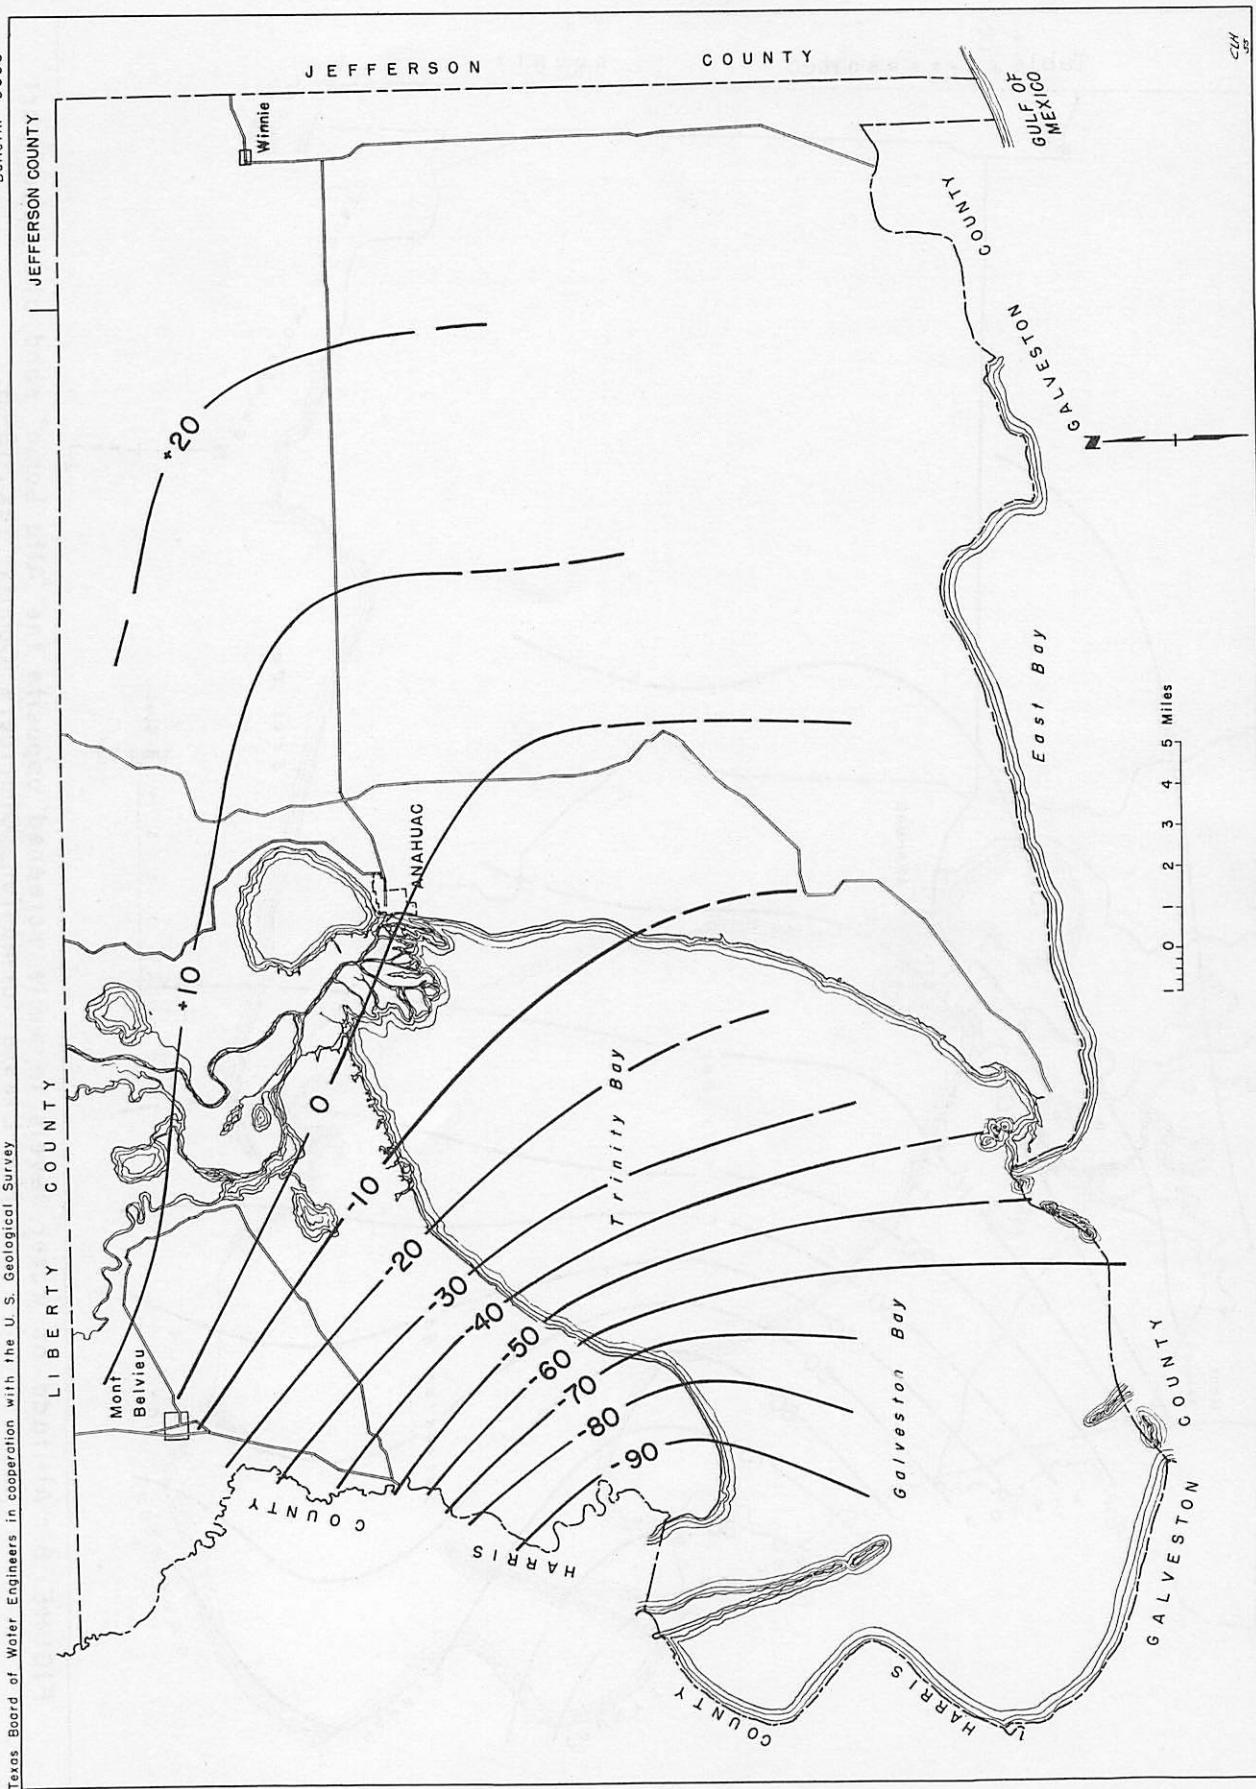

FIGURE 9.-Altitude of water levels in wells screened opposite the "Alta Loma" sand and upper part of the Lissie formation, Chambers County, Tex., 1954.

Table 1.--Estimated use of ground water during 1948  
in Chambers County, Tex.

Use	Estimated withdrawal (gal. per day)
Domestic supplies	525,000
Public supplies	130,000
Industrial supplies	150,000
Livestock	50,000
Total	855,000

#### CONCLUSIONS

Small quantities of potable ground water can be obtained from shallow wells throughout most of Chambers County. Larger supplies of water can be obtained from deeper wells, but in the eastern half of the county the mineral content of the water increases to an objectionable amount. Sufficient quantities of water suitable for drilling oil tests are available throughout the county.

Although only small supplies of potable ground water are available from sands in the Beaumont clay throughout most of Chambers County, some local areas, such as Winnie, have relatively large supplies. The "Alta Loma" sand underlying southwestern Chambers County, including a portion of Galveston Bay, is probably capable of yielding sufficient quantities of water to supply industries having moderate water requirements. Sands below the "Alta Loma" in Chambers County are capable of yielding large quantities of moderately to highly mineralized water.
